Generative Adversarial Networks

Statistical Generative Models

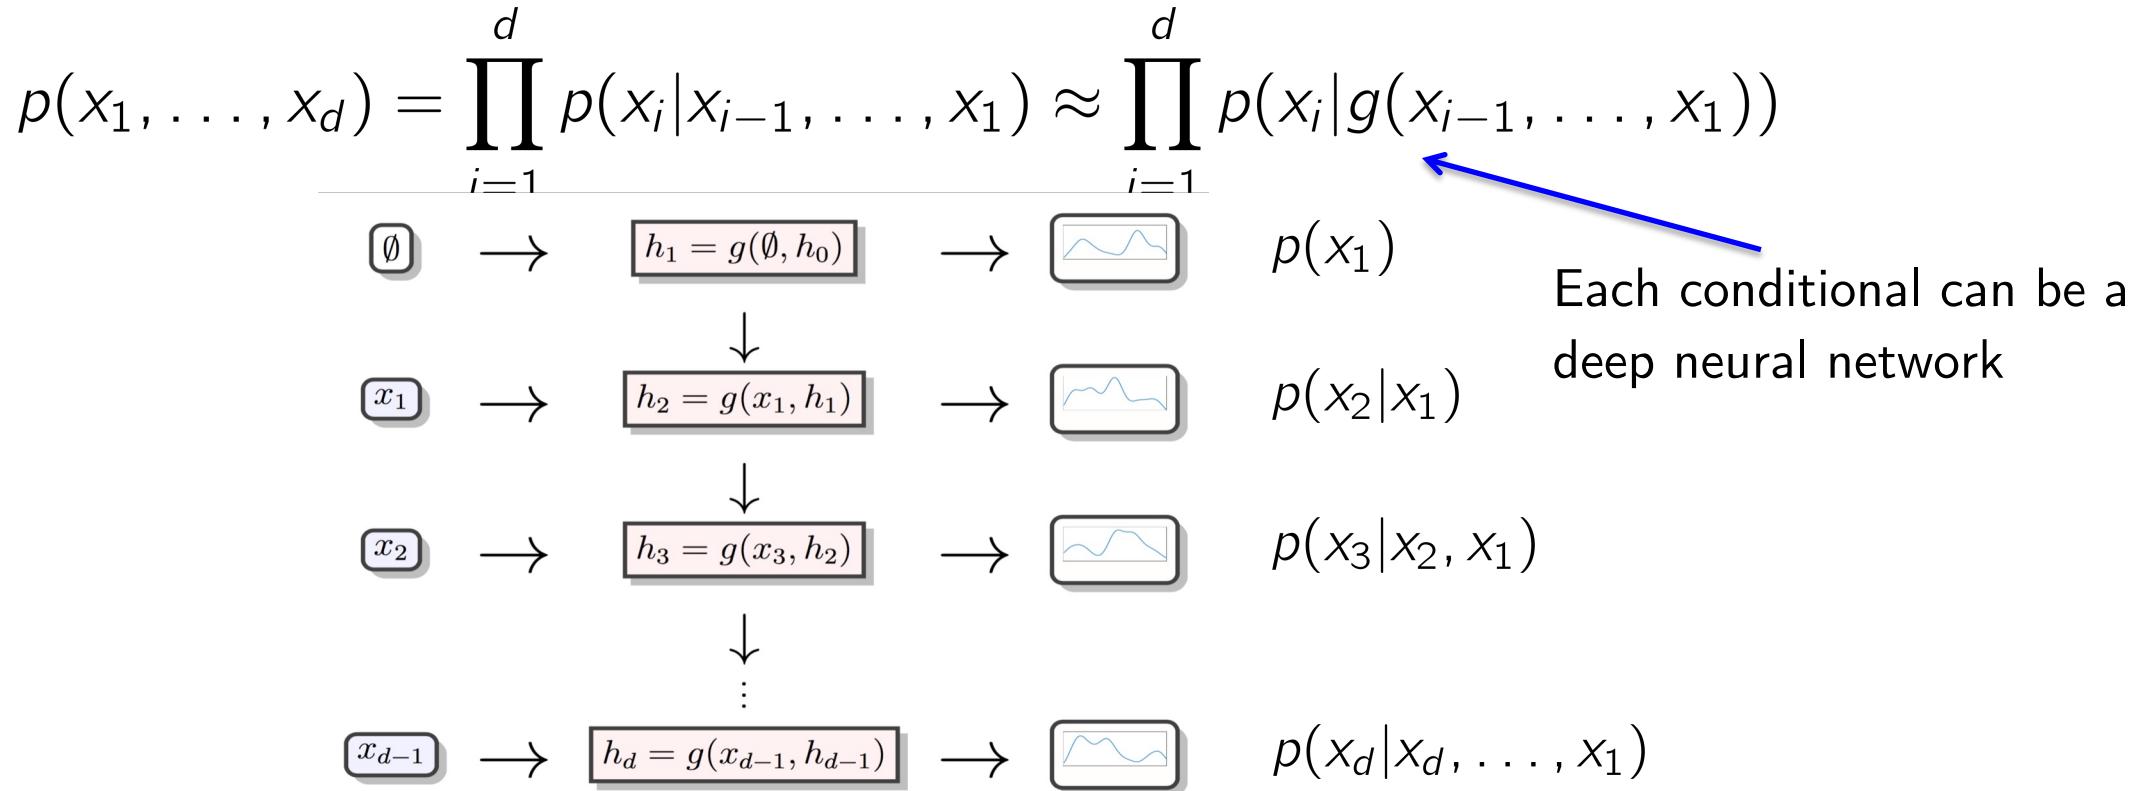

+

Model family, loss function,
optimization algorithm, etc.

Fully Observed Models

- Density Estimation by Autoregression

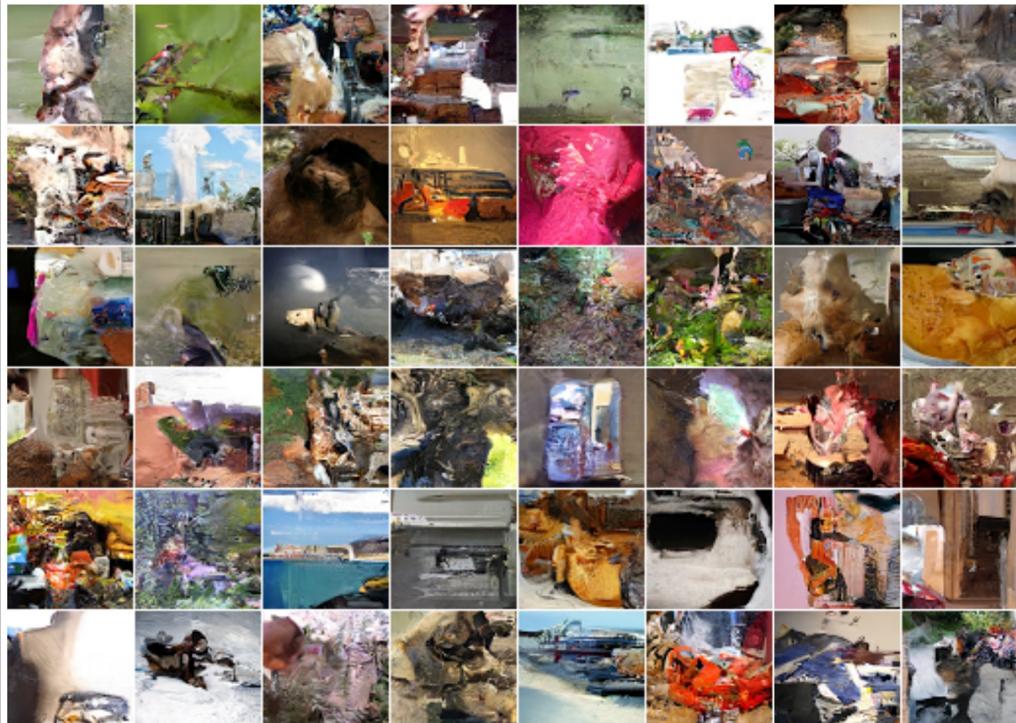

- Ordering of variables is crucial

NADE (Uria 2013), MADE (Germain 2017), MAF (Papamakarios 2017), PixelCNN (van den Oord, et al, 2016)

Fully Observed Models

- Density Estimation by Autoregression

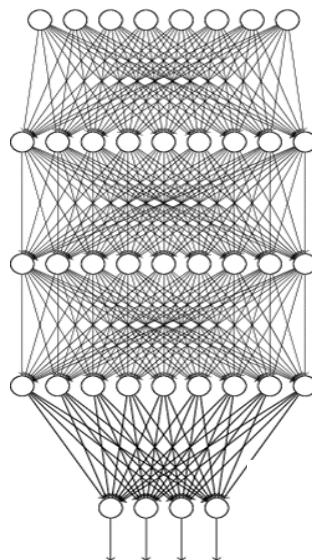

PixelCNN (van den Oord, et al, 2016)

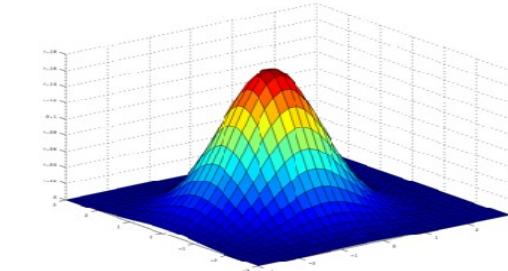

NADE (Uria 2013), MADE (Germain 2017), MAF (Papamakarios 2017), PixelCNN (van den Oord, et al, 2016)

Deep Directed Generative Models

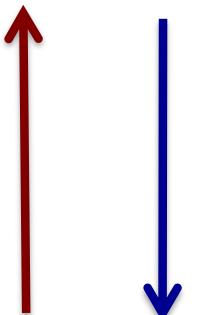

White
Noise

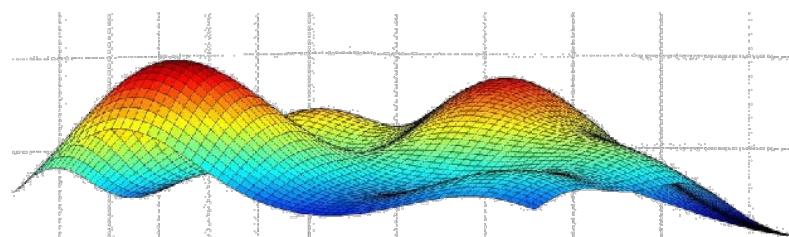

Code Z

- ▶ Recognition
- ▶ Bottom-up
- ▶ $Q(z|x)$

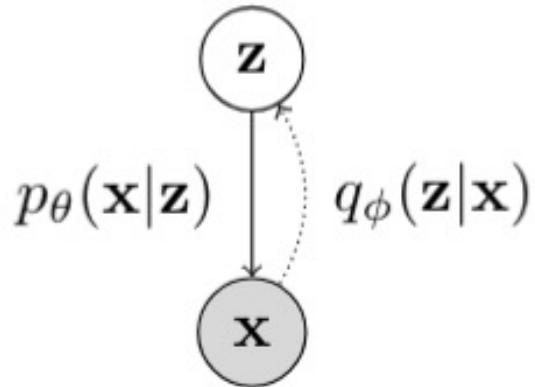

- ▶ Generative
- ▶ Top-Down
- ▶ $P(x|z)$

D_{real}

- ▶ Latent Variable Models

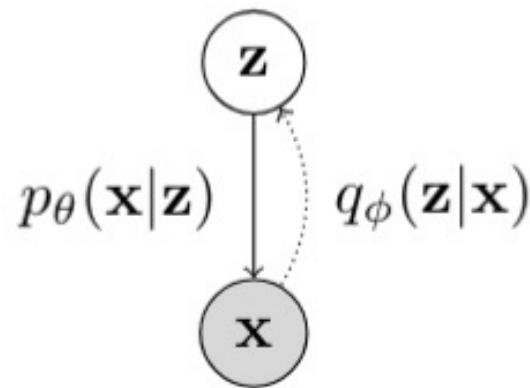

$$\log p_\theta(\mathbf{x}) = \log \int p_\theta(\mathbf{x}, \mathbf{z}) d\mathbf{z}$$

- ▶ Conditional distributions are parameterized by deep neural networks

Directed Deep Generative Models

- Directed Latent Variable Models with Inference Network

- Maximum log-likelihood objective

$$\max_{\theta} \sum_{\mathbf{x} \in \mathcal{D}} \log p_{\theta}(\mathbf{x})$$

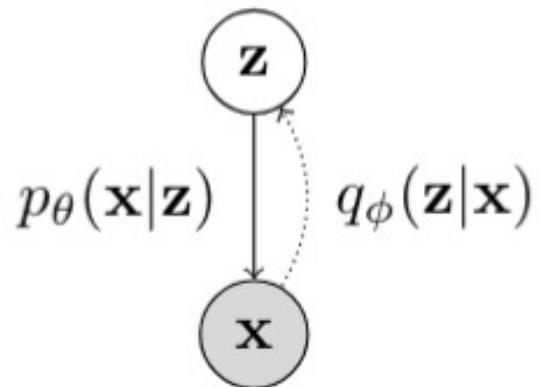

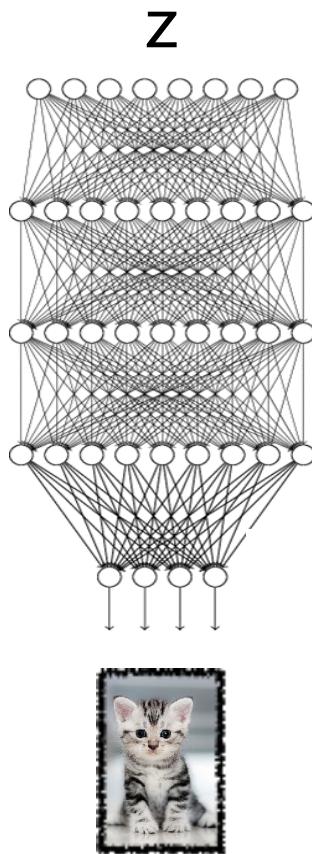

- Marginal log-likelihood is **intractable**:

$$\log p_{\theta}(\mathbf{x}) = \log \int p_{\theta}(\mathbf{x}, \mathbf{z}) d\mathbf{z}$$

- **Key idea:** Approximate true posterior $p(z|x)$ with a simple, tractable distribution $q(z|x)$ (inference/recognition network).

Variational Autoencoders (VAEs)

- Single stochastic (Gaussian) layer, followed by many deterministic layers

$$p(\mathbf{z}) = \mathcal{N}(0, I)$$

$$p_{\theta}(\mathbf{x}|\mathbf{z}) = \mathcal{N}(\mu(\mathbf{z}, \theta), \Sigma(\mathbf{z}, \theta))$$

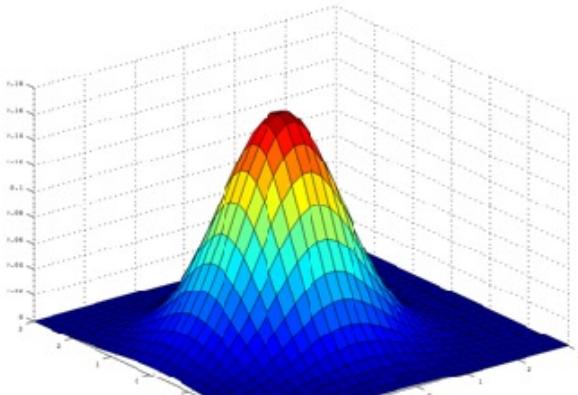

Deep neural network parameterized by θ
(Can use different noise models)

$$q_{\phi}(\mathbf{z}|\mathbf{x}) = \mathcal{N}(\mu(\mathbf{x}, \phi), \Sigma(\mathbf{x}, \phi))$$

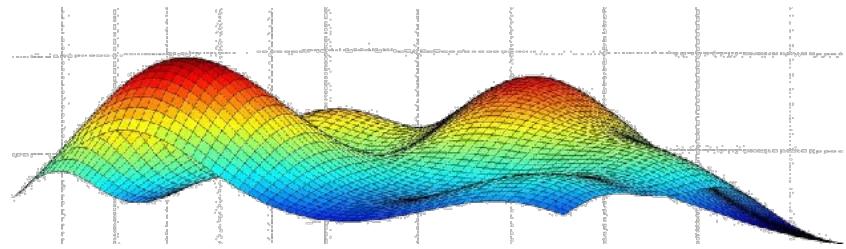

Deep neural network parameterized by ϕ

Generative Adversarial Networks (GAN)

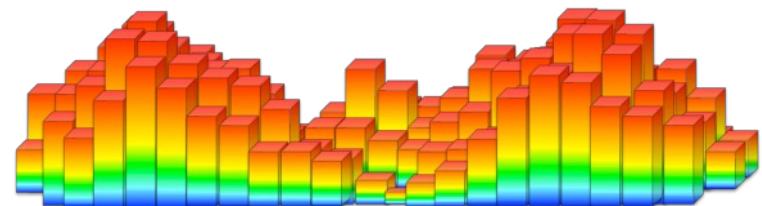

- ▶ Implicit generative model for an unknown target density $p(x)$
- ▶ Converts sample from a known noise density $p_Z(z)$ to the target $p(x)$

Noise density $p_Z(z)$ over space \mathcal{Z}

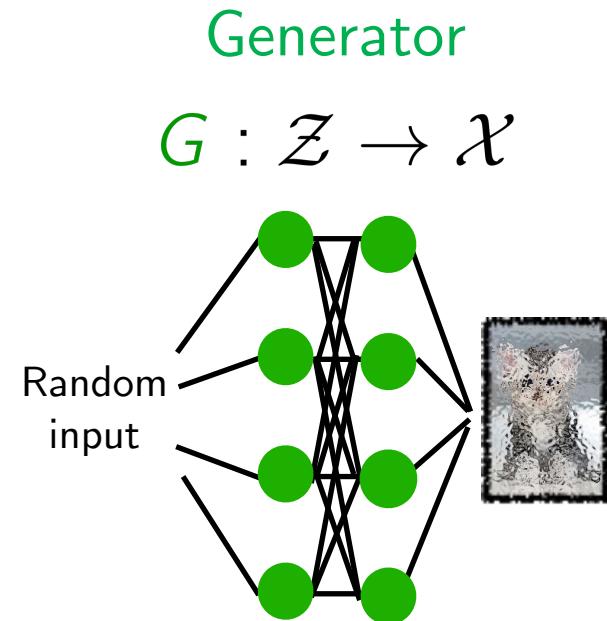

Unknown target density $p(x)$ of data over domain \mathcal{X} , e.g. $\mathbb{R}^{32 \times 32}$

Distribution of generated samples should follow target density $p(x)$

GAN Formulation

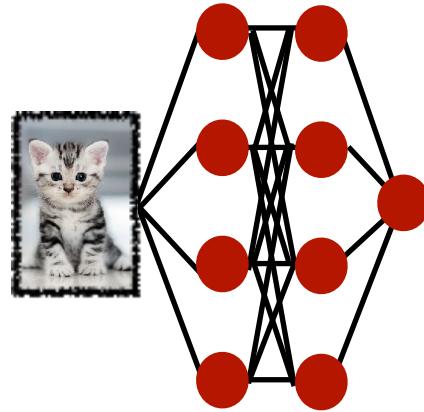

- GAN consists of two components

Goal: Produce samples
indistinguishable from true data

Discriminator

$$D : \mathcal{X} \rightarrow \mathbb{R}$$

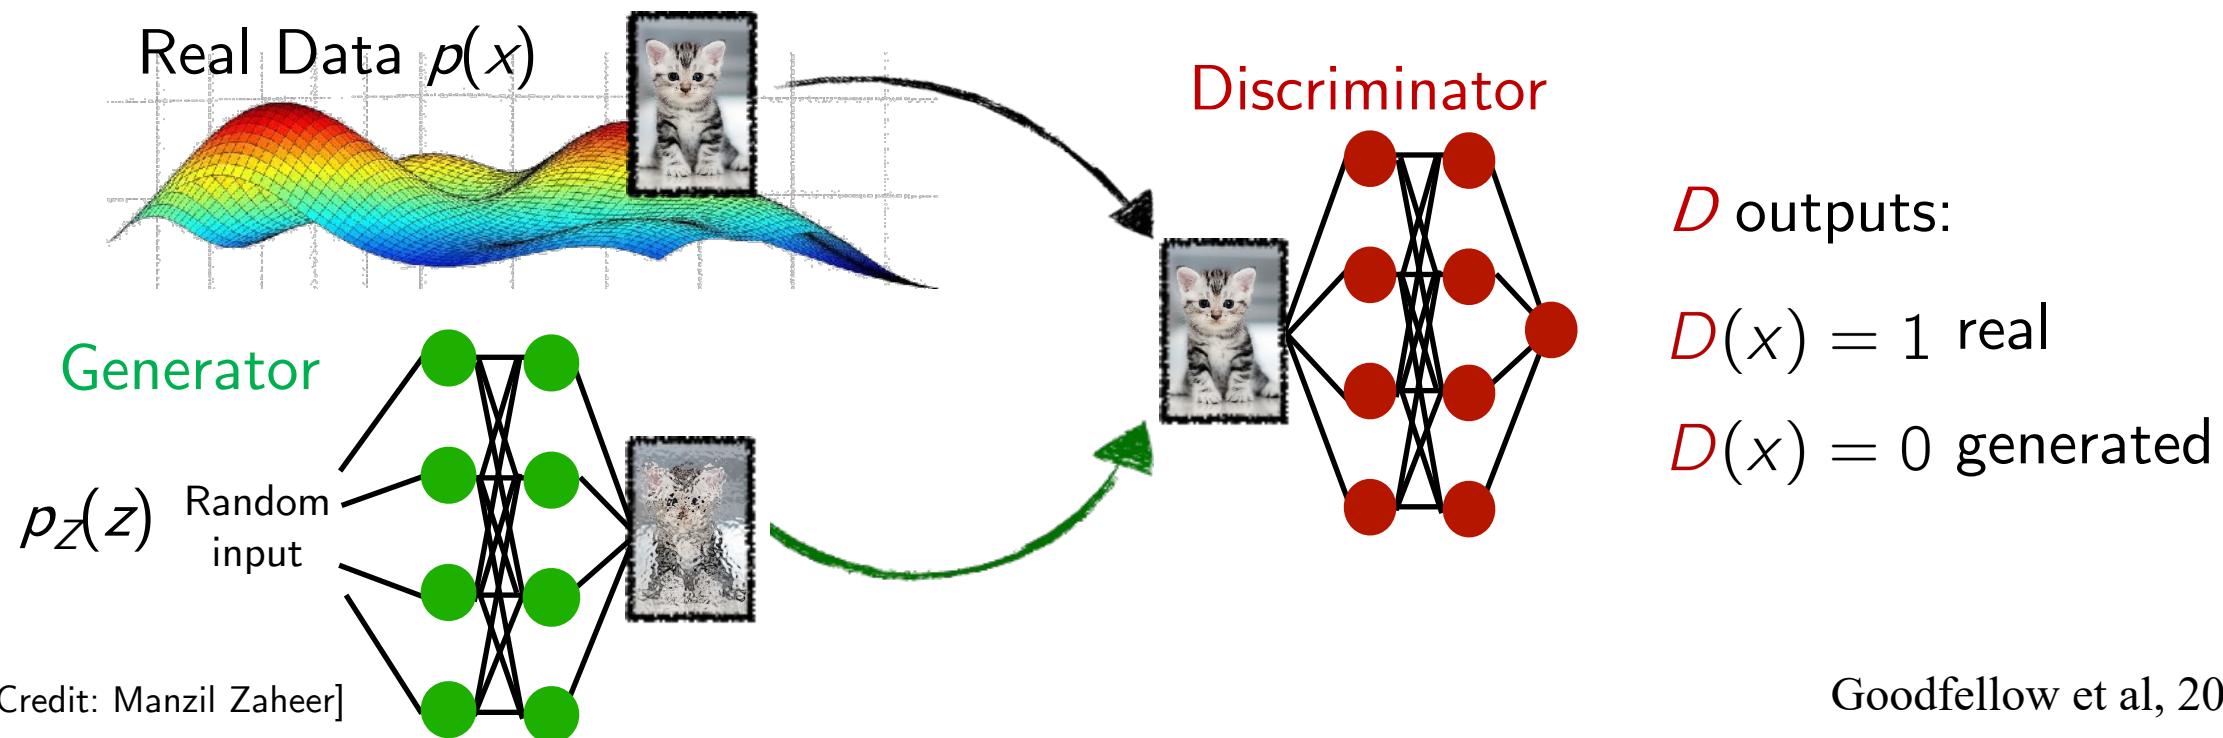

Goal: Distinguish
true and generated
data apart

GAN Formulation: Discriminator

- Discriminator's objective: Tell real and generated data apart like a classifier

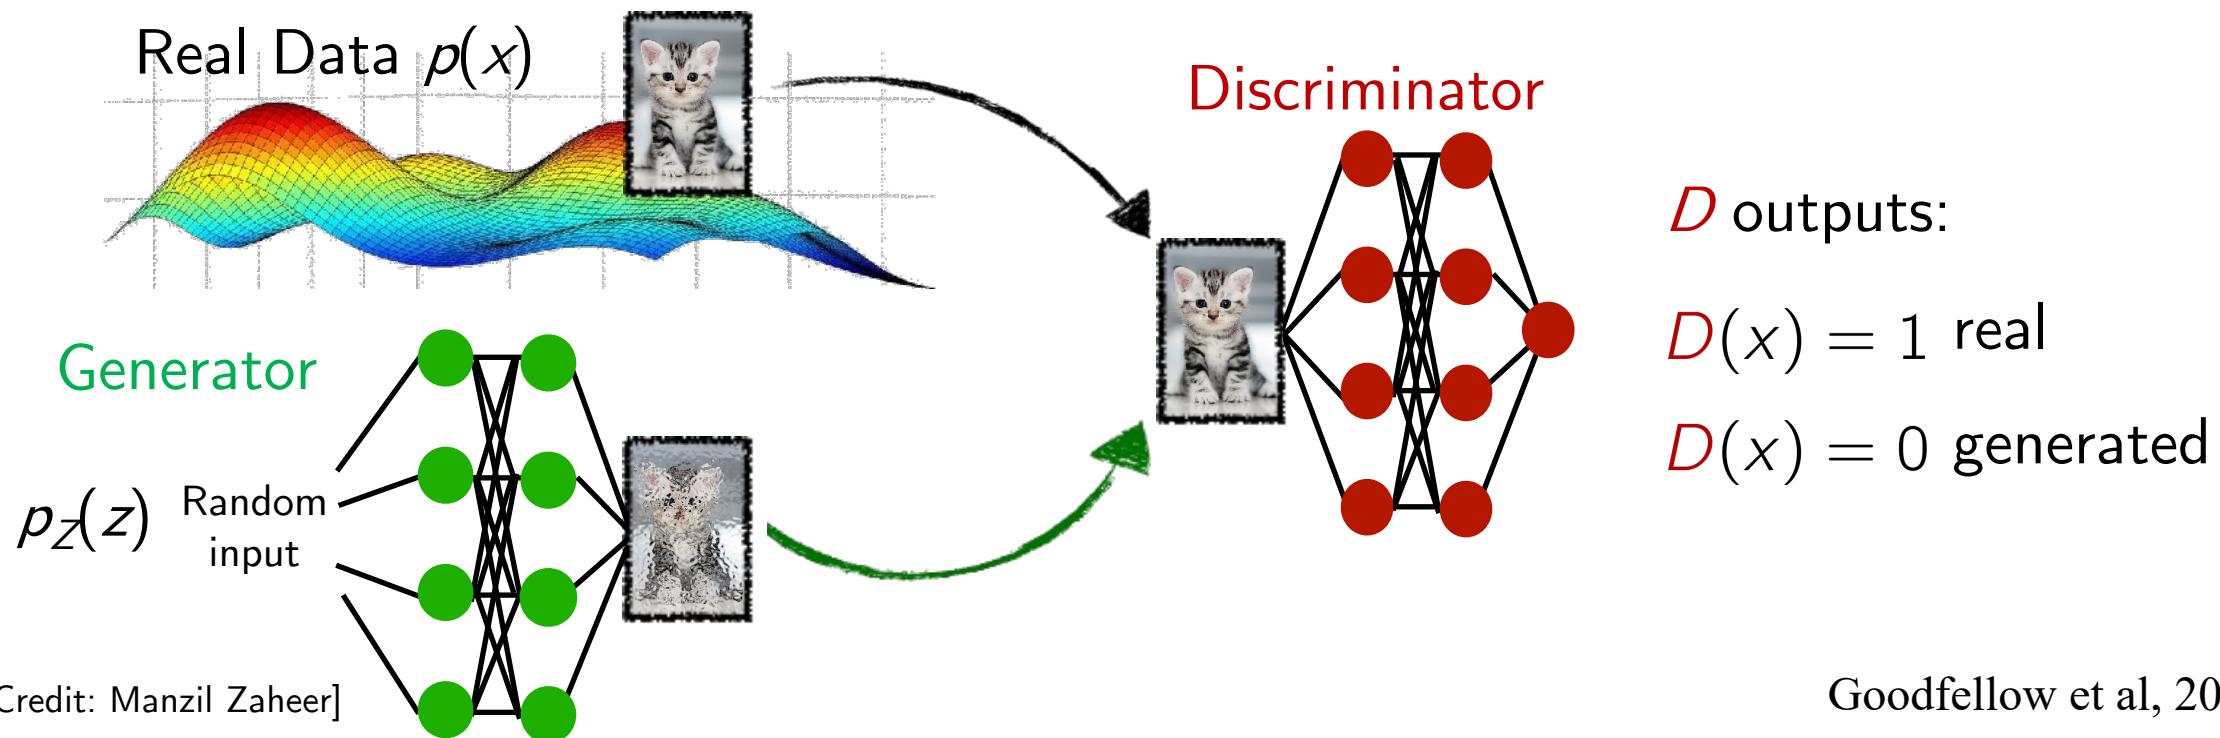

$$\max_D \mathbb{E}_{x \sim p} [\log D(x)] + \mathbb{E}_{z \sim p_Z} [\log (1 - D(G(z)))]$$

GAN Formulation: Generator

- Generator's objective: Fool the best **discriminator**

$$\min_G \max_D \mathbb{E}_{x \sim p} [\log D(x)] + \mathbb{E}_{z \sim p_Z} [\log (1 - D(G(z)))]$$

GAN Formulation: Optimization

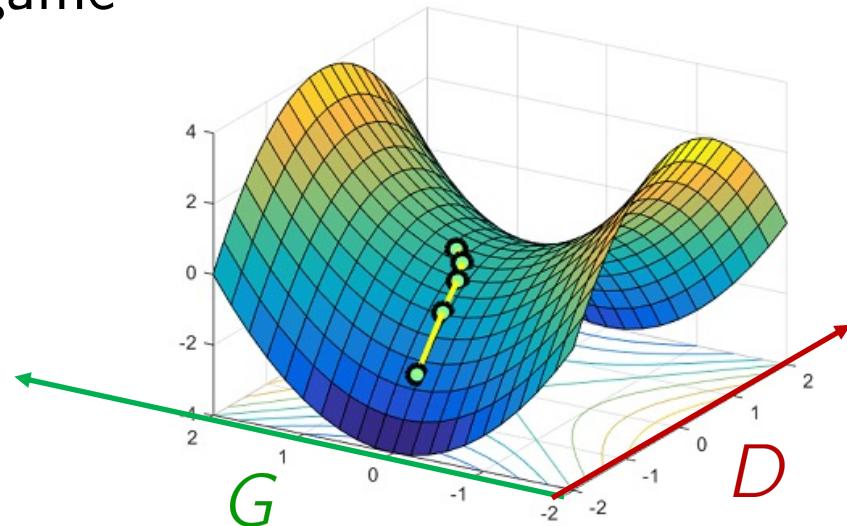

- ▶ Overall GAN optimization

$$\min_G \max_D V(G, D) = \mathbb{E}_{x \sim p} [\log D(x)] + \mathbb{E}_{z \sim p_Z} [\log (1 - D(G(z)))]$$

- ▶ The generator-discriminator are iteratively updated using SGD to find “equilibrium” of a “min-max objective” like a game

$$G \leftarrow G - \eta_G \nabla_G V(G, D)$$

$$D \leftarrow D - \eta_D \nabla_D V(G, D)$$

Distributional perspective - Discriminator

$$\min_G \max_D V(G, D) = \mathbb{E}_{\mathbf{x} \sim p_{\text{data}}} [\log D(\mathbf{x})] + \mathbb{E}_{\mathbf{z} \sim p(\mathbf{z})} [\log(1 - D(G(\mathbf{z})))]$$

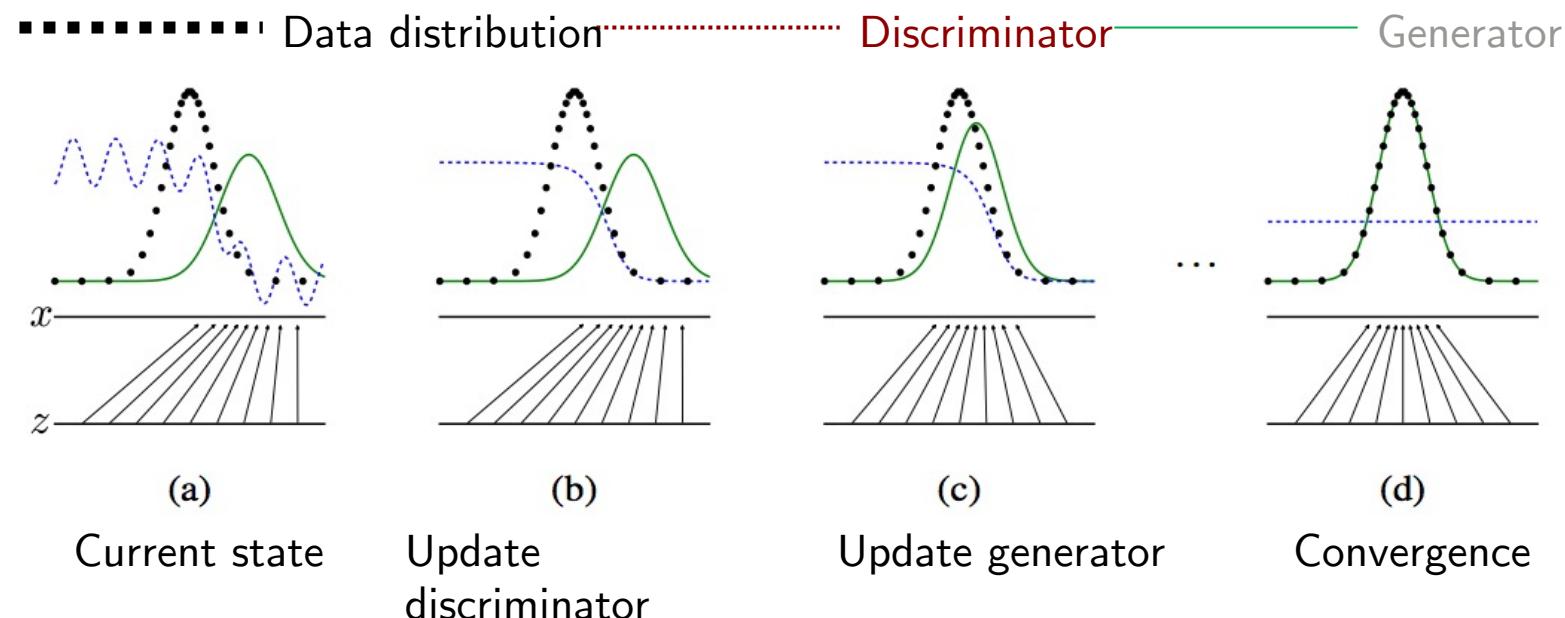

- ▶ For a fixed generator, discriminator is maximizing negative cross entropy
- ▶ Optimal discriminator is given by:

$$D_G^*(\mathbf{x}) = \frac{p_{\text{data}}(\mathbf{x})}{p_{\text{data}}(\mathbf{x}) + p_g(\mathbf{x})}$$

A minimax learning objective

- During learning, generator and discriminator are updated alternatively

$$\min_{\theta} \max_{\phi} V(G_{\theta}, D_{\phi}) = \mathbb{E}_{\mathbf{x} \sim p_{\text{data}}} [\log D_{\phi}(\mathbf{x})] + \mathbb{E}_{\mathbf{z} \sim p(\mathbf{z})} [\log(1 - D_{\phi}(G_{\theta}(\mathbf{z})))]$$

Evaluation

- ▶ Likelihoods may not be defined or tractable
- ▶ Directed model permits ancestral sampling
 - ▶ For labelled datasets, metrics such as inception scores quantify sample diversity and quality using pretrained classifiers

Mode Collapse

- ▶ In practice, GANs suffer from mode collapse

Arjovsky et al., 2017

Wasserstein GAN

- ▶ WGAN optimization

$$\min_G \max_D W(G, D) = \mathbb{E}_{x \sim p} [D(x)] - \mathbb{E}_{z \sim p_Z} [D(G(z))]$$

- ▶ Difference in expected output on real vs. generated images
 - ▶ Generator attempts to drive objective ≈ 0
- ▶ More stable optimization

Compare to training DBMs

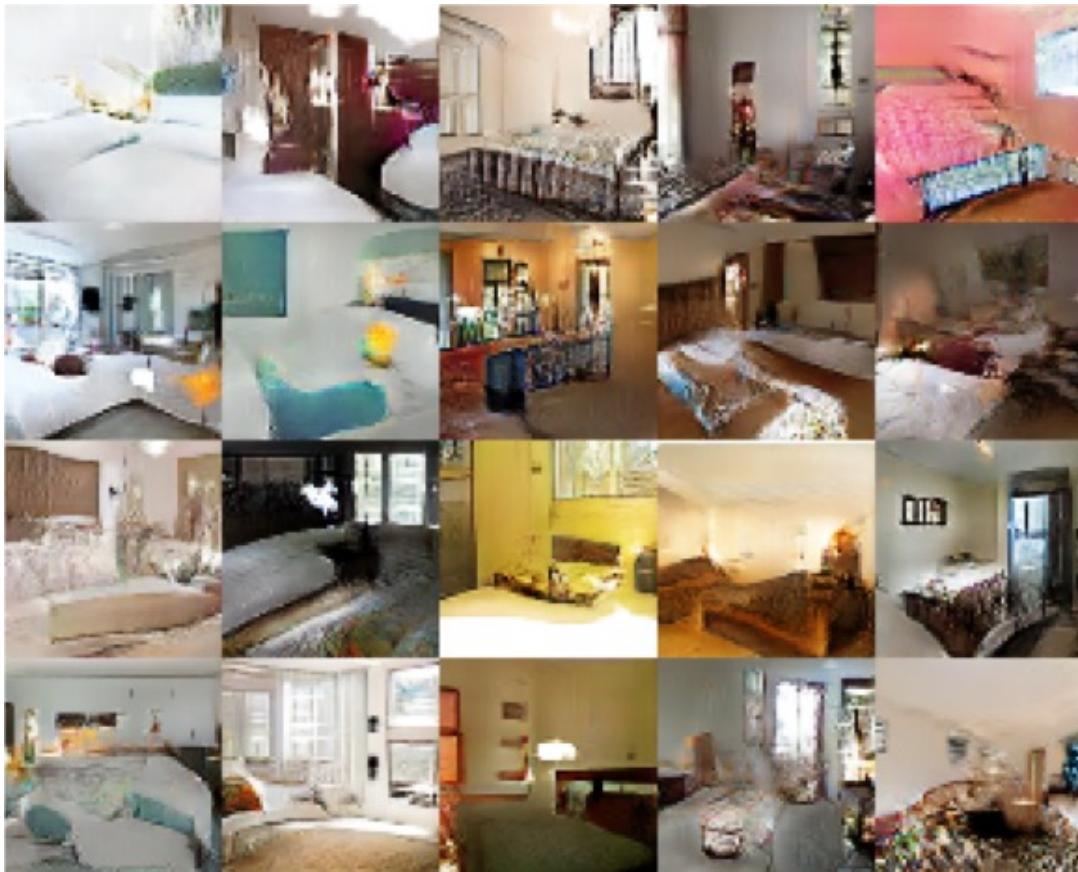

$$\frac{\partial \log P_\theta(\mathbf{v})}{\partial W^1} = \mathbb{E}_{P_{data}} [\mathbf{v} \mathbf{h}^1] - \mathbb{E}_{P_\theta} [\mathbf{v} \mathbf{h}^1]$$

D outputs:

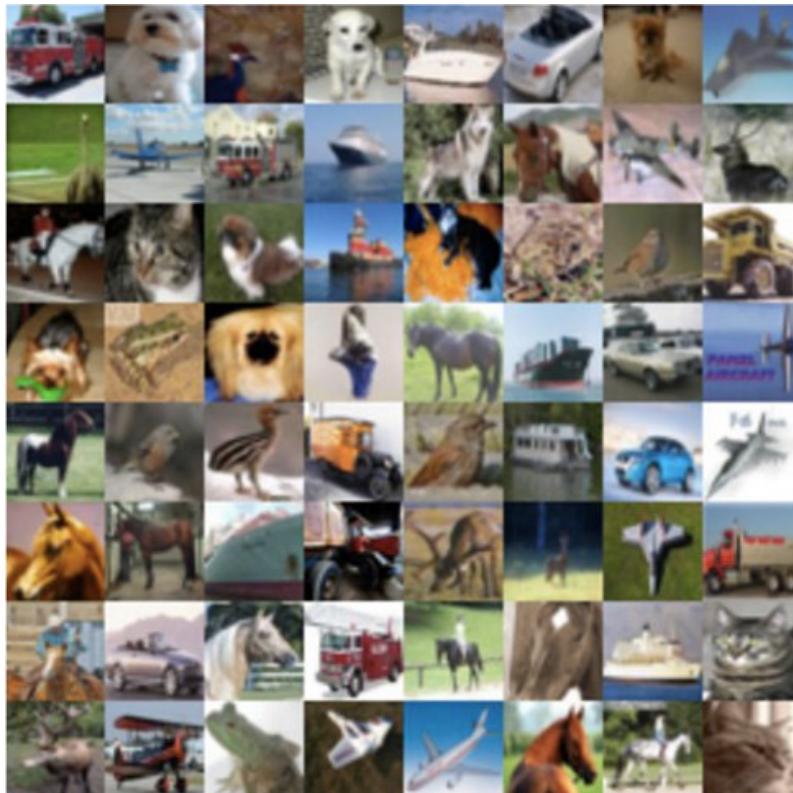

$D(x) = 1$ real

$D(x) = 0$ generated

Normalizing Flows

- Directed Latent Variable Invertible models

- The mapping between x and z is deterministic and invertible:

$$\mathbf{x} = \mathbf{f}_\theta(\mathbf{z})$$

$$\mathbf{z} = \mathbf{f}_\theta^{-1}(\mathbf{x})$$

- Use change-of-variables to relate densities between z and x

$$p_X(\mathbf{x}; \theta) = p_Z(\mathbf{z}) \left| \det \frac{\partial \mathbf{f}_\theta^{-1}(\mathbf{x})}{\partial \mathbf{X}} \right|_{\mathbf{X}=\mathbf{x}}$$

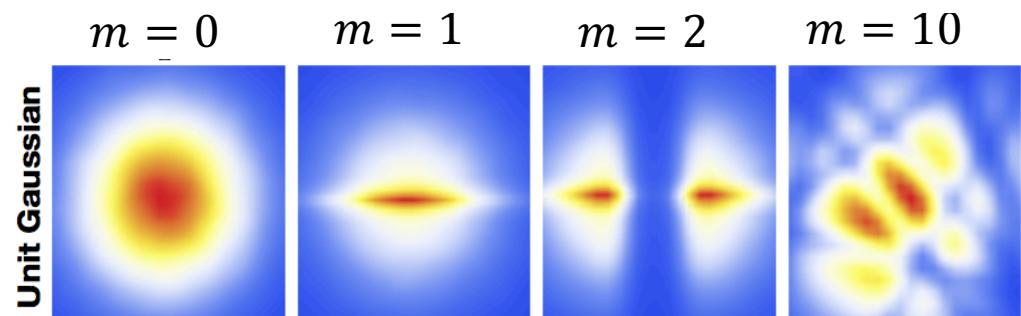

Normalizing Flows

- Invertible transformations can be composed:

$$\mathbf{x} = \mathbf{f}_\theta^M \circ \dots \circ \mathbf{f}_\theta^1(\mathbf{z}^0); \quad p_X(\mathbf{x}; \theta) = p_{Z^0}(\mathbf{z}^0) \prod_{m=1}^M \left| \det \frac{\partial (\mathbf{f}_\theta^m)^{-1}}{\partial Z^m} \right|_{Z^m=\mathbf{z}^m}$$

- Planar Flows

$$f(\mathbf{z}) = \mathbf{z} + \mathbf{u}g(\mathbf{w}^\top \mathbf{z} + b)$$

Rezende and Mohamed, 2016

Normalizing Flows

- ▶ Maximum log-likelihood objective

$$\max_{\theta} \log p_X(\mathcal{D}; \theta) = \sum_{\mathbf{x} \in \mathcal{D}} \left(\log p_Z(\mathbf{z}) - \log \left| \det \frac{\partial (\mathbf{f}_{\theta})^{-1}}{\partial X} \right|_{X=\mathbf{x}} \right)$$

- ▶ Exact log-likelihood evaluation via inverse transformations
- ▶ Sampling from the model

$$\mathbf{z} \sim p_Z(\mathbf{z}), \quad \mathbf{x} = \mathbf{f}_{\theta}(\mathbf{z})$$

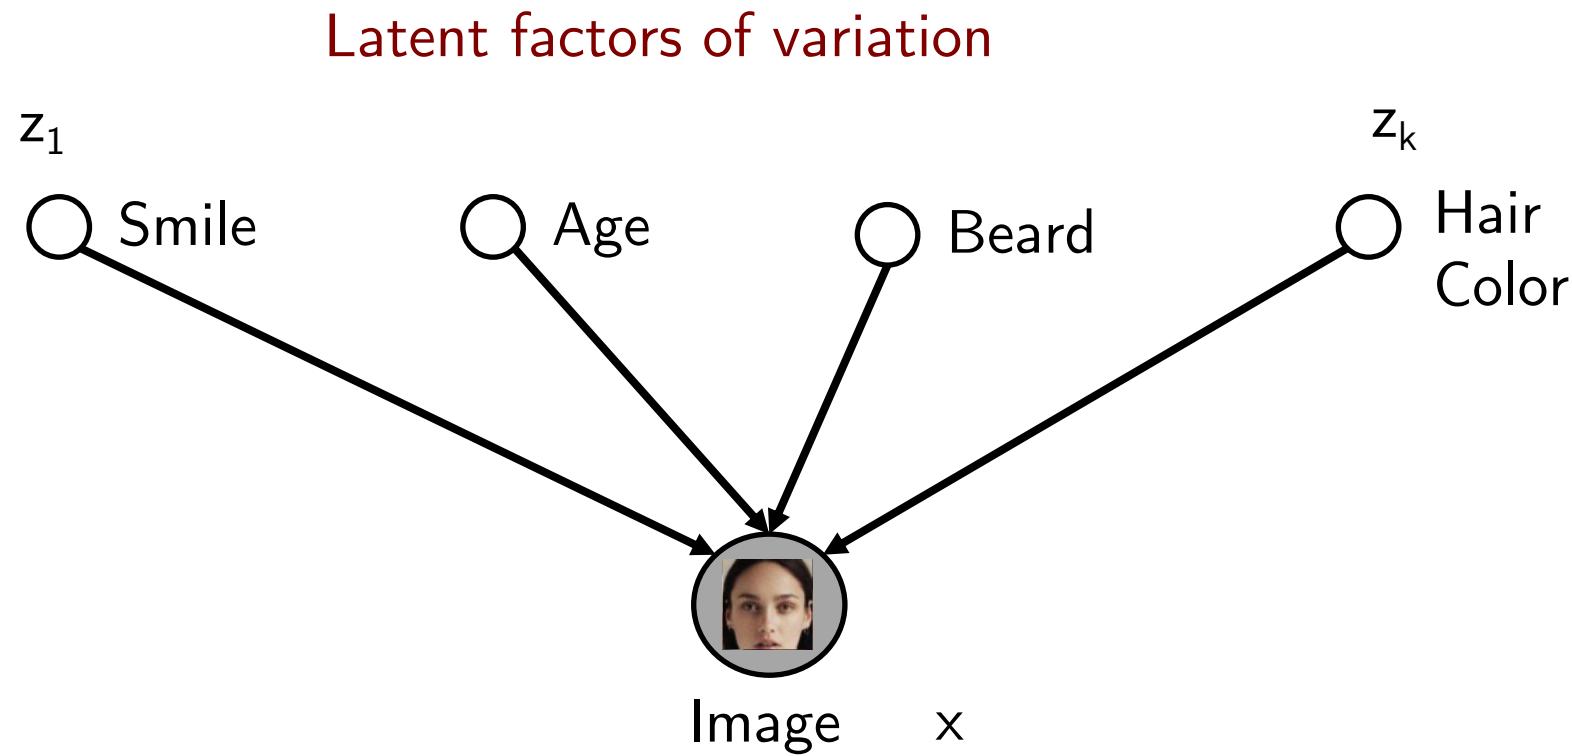

- ▶ Inference over the latent representations:

$$\mathbf{z} = \mathbf{f}_{\theta}^{-1}(\mathbf{x})$$

Example: GLOW

- Generative Flow with Invertible 1x1 Convolutions

<https://blog.openai.com/glow/>

Flow Models

- ▶ Simple prior that allows for sampling and tractable likelihood evaluation
e.g., isotropic Gaussian
- ▶ Invertible transformations with tractable evaluation:
 - ▶ Likelihood evaluation requires efficient evaluation of inverse
 - ▶ Sampling requires efficient evaluation of inverse
- ▶ Tractable evaluation of determinants of Jacobian for large models
 - ▶ Computing determinants for a large matrix is prohibitive
 - ▶ Key idea: Determinant of triangular matrices is the product of the diagonal entries, i.e., an $\mathcal{O}(n)$ operation
